## Dental Implant Surgery

By Frank Denber

If you have to replace missing teeth and need an implant, then you should know that there is a new revolutionary dental implant technique which reduces treatment time and pain dramatically. The "Teeth-in-an-Hour" program of Nobel Biocare gives you a new tooth within just one treatment and a short surgery.

The traditional ways to do implants is by implanting an anchor into the jawbone first. Then, after a healing period of several weeks or months, the bone has grown around the anchor and the implant can be set. This usually takes another surgery and another healing period. Then the denture is fixed to the implant and your tooth or bridge is ready.

Such implants are usually made of titanium but can also be made of porcelain. Titanium is a very long lasting, durable material and ideal for implant surgery to replace missing teeth. The anchor works as an artificial root for a new tooth. This can be a beautiful porcelain crown for example which looks very natural.

A missing tooth should always be replaced because the gap destabilizes the surrounding teeth. The gap is not only an aesthetical issue. With time, the bone weakens at this area and grows back, together with the muscles attached to this bone. The faster you replace the tooth the better.

There have been great advances in dental implant surgery recently. One invention from Biocare has changed the implant technology quite a bit. The secret lies in finding the best and strongest point for the implant in the jawbone. This reduces the required drilling to a minimum. To achieve this, a CT Scan is done which is then analyzed by a sophisticated software. The perfect points are marked and a custom made prothesis is manufactured. The dentist then uses this prothesis together with a detailed drill guide to make a perfect, clean little surgery. There is no more waiting until the artificial tooth can be attached to the implant.

With very little pain, less time and minimal trauma, the patient leaves the chair with a new functional tooth in place. This method was FDA approved in 2004, which means it has been clinically documented. The costs for this dental implant surgery are not much higher than for the traditional

surgery. Cosmetic dentists get trainings from Biocare so that more and more dentists offering these new implant technique worldwide.

The costs for dental implants are about \$1200 to \$3000 per tooth.

### **Dental Implants Procedures**

**By Chris Miller**

Dental implants are created by putting a titanium implant into the jaw and connecting a ceramic crown once the jaw has fused the implant. Once this occurs, the dental implant is secured in place.

A wide variety of techniques can be utilized depending on the state of the implant site. One quick method can be completed in one single day, and can be done if the tooth is replaced in a healthy gum over good bone. Grafting or growing new bone is considered very complex and can take up to half a year or longer to do.

If a tooth needs to be extracted because it is decayed or damaged, as long as the surrounding gum is not damaged, the dental implant may be installed the same time as when the broken tooth is removed. This procedure will typically include a temporary crown and later replaced with a permanent crown once the bone fusion is complete. While healing, it may be best to avoid certain foods after the dental implant has been installed.

Common dental implants occur through a process of stages. An implant is installed to the jaw bone and will need to fuse for roughly 3–6 months. Once this stage is complete, a post, known as an abutment, is put in the implant. Then the casts are removed off of the teeth and a crown made to match the existing tooth is adhered to the abutment.

When the bone structure is weak, one of the most complicated dental implant procedures can take place. In some cases a bone graft might be needed, or the bone can be stimulated to grow. The bone must be allowed to heal before the dental implant is installed. This can make the process very lengthy.

A custom fit plate can be placed between the jaw and gum if the bone structure is not in good condition for a dental implant. In order to obtain accurate measurements a CAT scan may be utilized or a cast cane be made by exposing the jaw.

Visit with your dentist to discuss which dental implant procedure is right for you. Your dentist could possibly perform the surgery at their office, or in more extreme cases, you may be referred to a periodontist.
